

MATH 590 2023 FALL REPORT

HONGDA LI

November 18, 2023

Abstract

In this paper, we review the paper written by Walkington [1] on the topic of proximal gradient with Nesterov accelerations. We compare the performance of the FISTA method and some of its variants with numerical experiments on the total variation minimization problem; in addition, we propose a heuristic estimation of the strong convexity parameter and demonstrate that it converges faster when applied. We give a literature review on the frontier for both the theories and applications around FISTA. We correct one misconception that occurred in Walkington [1] regarding Nesterov's proof of lower bound on the optimality of first-order algorithms. We present a better proof of linear convergence of FISTA under strong convexity assumption from Beck [2, theorem 10.7.7] by eliminating an identity used in their proof. Finally, we use the Forward Backward Envelope to adapt smooth non-smooth additive objective to Nesterov's generic accelerated gradient algorithm [3, 2.2.7].

1 Preliminaries

In this section, We initiate the discussion by denoising a one-dimensional signal. The dual objective function of the problem derived in this section motivates the use of Accelerated Proximal Gradient with smooth, non-smooth composite objective function. We summarized it from Walkington [1], sections 1 and 4.

1.1 Signal Denoising in One Dimension

Let a one dimensional signal be $u : [0, 1] \mapsto \mathbb{R}$ and u . Regularizing the derivative of the signal using the L1 norm helps recover the digital signal if it's a piecewise constant function. This is called a Total Variation (TV) minimization. Let \hat{u} denote an observation of u corrupted by noise. The denoised signal is the minimizer of $f(u)$,

$$f(u) = \int_0^1 \frac{1}{2}(u - \hat{u})^2 + \alpha |u'| dt.$$

Practical implementations for modern computing devices would necessitate discretization of the integral.

We use the trapezoidal rule and second-order forward difference for the derivative. Let $\hat{u} \in \mathbb{R}^{N+1}$, a vector in the form of $\hat{u} = [\hat{u}_0 \ \cdots \ \hat{u}_N]$, let $t_0 < \cdots < t_N$ be a sequence of time corresponded to each observation of \hat{u}_i . The time intervals are $h_i = t_i - t_{i-1}$ for $i = 1, \dots, N$, not necessarily equally spaced, making this formulation below is slightly more general than Walkington[1]. We derive the

approximation of the integral. Denote $s_i = u_i - \hat{u}_i$.

$$\begin{aligned}
\frac{1}{2} \int_0^1 (u - \hat{u})^2 dt + \alpha \int_0^1 |u'| dt &\approx \frac{1}{2} \sum_{i=0}^N \left(\frac{s_i^2 + s_{i+1}^2}{2} \right) h_{i+1} + \alpha \sum_{i=1}^N \left| \frac{u_i - u_{i-1}}{h_{i+1}} \right| \\
&\triangleright \text{let } C \in \mathbb{R}^{N \times (N+1)} \text{ be upper bi-diagonal with } (1, -1) \\
&= \frac{1}{2} \left(\frac{s_0^2 h_1}{2} + \frac{s_N^2 h_N}{2} + \sum_{i=1}^{N-1} s_i^2 h_i \right) + \alpha \|Cu\|_1 \\
&\triangleright \text{using } D \in \mathbb{R}^{N \times (N+1)}, \\
&\triangleright D := \text{diag}(h_1/2, h_1, h_2, \dots, h_N, h_N/2) \\
&= \frac{1}{2} \langle u - \hat{u}, D(u - \hat{u}) \rangle + \alpha \|Cu\|_1.
\end{aligned}$$

28 The above formulation suggests a smooth, non-smooth additive composite objective for $f(u)$. The
 29 Proximal Gradient method and its variants can solve this optimization problem. Unfortunately,
 30 the non-smooth part $\alpha \|Cu\|_1$ presents computational difficulty if matrix C is unfriendly for the
 31 prox operator. One way to bypass the difficulty involves reformulating with $p = Cu$ and solving
 32 the dual problem.

33 Dual Reformulation

34 Let $p = Cu$, $C \in \mathbb{R}^{(N+1) \times N}$ with $D \in \mathbb{R}^{(N+1) \times (N+1)}$, we reformulate it into

$$\min_{u \in \mathbb{R}^{N+1}} \left\{ \underbrace{\frac{1}{2} \langle (u - \hat{u}), D(u - \hat{u}) \rangle}_{f(u)} + \underbrace{\alpha \|p\|_1}_{h(p)} \mid p = Cu \right\},$$

35 producing Lagrangian of the form

$$\mathcal{L}((u, p), \lambda) = f(u) + h(p) + \langle \lambda, p - Cu \rangle.$$

The dual is

$$\begin{aligned}
-g(\lambda) &:= \inf_{(u, p) \in \mathbb{R}^{N+1} \times \mathbb{R}^N} \{ \mathcal{L}((u, p), \lambda) \} \\
&= \inf_{(u, p) \in \mathbb{R}^{N+1} \times \mathbb{R}^N} \{ f(u) + h(p) + \langle \lambda, p - Cu \rangle \} \\
&= \inf_{u \in \mathbb{R}^{N+1}} \left\{ f(u) - \langle \lambda, Cu \rangle + \inf_{p \in \mathbb{R}^N} \{ h(p) + \langle \lambda, p \rangle \} \right\} \\
&\leq -f^*(-C^T \lambda) - h^*(p).
\end{aligned}$$

36 The theorem of strong duality applies hence equality. With the assumption that D is positive
 37 definite, we have

$$-g(\lambda) = -\frac{1}{2} \|C^T \lambda\|_{D^{-1}}^2 - \langle \hat{u}, C^T \lambda \rangle - \delta_{[-\alpha, \alpha]^N}(p).$$

Observe that the above admits a hyperbox indicator function that makes the prox operator friendlier because the proximal operator of the indicator is projection; in the case of projecting onto the box, the operator is simple. Given dual variable λ , primal is obtained by

$$\begin{aligned}
u &= \operatorname{argmin}_u \mathcal{L}((u, p), \lambda) \\
\partial_u \mathcal{L}((u, p), \lambda) &= D(u - \hat{u}) - C^T \lambda = \mathbf{0} \\
\implies u &= \hat{u} + D^{-1} C^T \lambda.
\end{aligned}$$

38 $-g(\lambda)$ is easier to optimize, and obtaining the primal solution is also simple since D^{-1} is a diagonal
39 matrix.

40 1.2 FISTA has Worse Convergence Guarantee for Strongly Convex Ob- 41 jectives

42 The dual objective for a total variation minimization problem is a strongly convex and Lipschitz
43 smooth function because of the norm induced by the positive definite matrix D^{-1} . It's in a form
44 where FISTA proposed by [4] can solve with a convergence rate of $\mathcal{O}(1/k^2)$ on the objective value
45 of the function. However, highlighted in Walkington[1], the proximal gradient method without
46 acceleration achieves $\mathcal{O}((1 - 1/\kappa)^k)$ convergence rate. Which is faster. The parameter κ is the
47 condition number; in this case, it would be L/α , where L is the Lipschitz smooth constant of $g(u)$
48 and α is the strong convexity constant for $g(u)$.

49 We emphasize that the Proximal Gradient without acceleration has better theoretical conver-
50 gence results than the accelerated version for the class of strongly convex objectives. It sparks
51 the discussion in this paper on the variants of FISTA, hoping to provide some insights on why
52 Nesterov's momentum-based method's inability to adapt the convergence rate with objective has
53 strong convexity. For the terminologies, we use FISTA to refer to the proximal gradient method
54 presented by Beck and Teboulle[4]. We use the Accelerated Proximal Gradient method (APG) to
55 refer to the first-order acceleration algorithms developed/inspired by FISTA.

56 Finally, whether the original FISTA[5] or Nesterov Accelerated gradient from 1983 has linear
57 convergence with the presence of strong convexity (or potentially other weaker conditions) is not
58 known during our research and literature review.

59 1.3 Outline of the Paper

60 Section 2 consists of 3 parts. The first part reviews the literature on the problem of Total Variation
61 (TV) minimization for image/signal denoising and deblurring. Presenting FISTA and its variants
62 is the second part. The third part reviews the algorithmic tricks and improvements applied to
63 the APG. Section 3 addresses a mistake made in Walkington's writing [1, theorem 2.4]. We will
64 discuss a first-order method and how a different function achieves the lower complexity bound on
65 the objective value and iterates for a fixed iteration. We discuss how omitting the details of this
66 theorem creates potential misconceptions of other frontier research ideas. Section 4 presents a proof
67 that I adapted from Amir Beck's writing [2, theorem 10.7.7]. The proof is slightly more general,
68 removing one equality to strengthen interpretability and generality. Section 5 presents plots of
69 convergence and results of applying variants of APG to the TV problem.

70 2 Literatures Review

71 2.1 Total Variation Minimizations

72 Rudin-Osher and Fatemi introduced the Total Variation (TV) minimization method in [6]. They
73 pioneer the theories of TV minimization by solving PDE. They discussed the empirical observation
74 that the L1 regularization term produces sharper images. Walkington [1] gives a basic formulation
75 of one-dimensional signal denoising. However, it's essential to keep in mind that this is a problem
76 that motivates a variety of modern computational methods and theories. We will list some of them
77 for context.

78 Goldstein et al. in [7, 3.2.1] showcased the dual reformulation of a 2D signal recovery with $\|\nabla u\|$
79 as the regularizations term. We note that this norm is without the squared. A more hardcore,

detailed coverage of reformulating the dual with L1 penalty terms for 2D signal recovery is in [5]. For a complete survey of the state of arts computational methods applied to TV minimizations, see Chambolle [8]. For a detailed exposition of mathematical theories regarding variational analysis on different types of TV problems and statistical inferences-based interpretations of the TV regularization term, consult the work by Chambolle et al.[9]. For frontier work of applying non-convex penalty term and its theoretical guarantee consult [10], [11].

Variants of FISTA

Walkington’s writing on the method of V-FISTA and accelerated gradient[1, section 4, section 3] consists of proofs that are too short and uninformative for good understanding. The frustration motivates us to look for better proofs of the algorithm’s convergence rate in other literature. It was a surprise that Walkington did not cite Nesterov’s new book[12]. We contextualize Walkington’s approach with Amir Beck’s book[2] and Nesterov’s book [12].

Different variants of FISTA differ by the sequence involved for their momentum method. Choosing different parameters in [algorithm 1](#) produces variants of FISTA.

Algorithm 1 Generic FISTA

```

1: Input:  $(g, h, x^{(0)})$ 
2:  $y^{(0)} = x^{(0)}, \kappa = L/\sigma$ 
3: for  $k = 0, 1, \dots$  do
4:    $x^{(k+1)} = \mathcal{T}_L y^{(k)}$ 
5:    $y^{(k+1)} = x^{(k+1)} + \theta_{k+1}(x^{(k+1)} - x^{(k)})$ 
6:   Execute subroutine  $\mathcal{S}$ .
7: end for

```

The scope of [algorithm 1](#) considers the additive composition of convex smooth and nonsmooth $f = g + h$ function with g being a L -smooth function. Changing $\mathcal{T}_L, \theta_{k+1}$ and \mathcal{S} , produce different variants of FISTA.

1. Original FISTA proposed by Beck [4] considers $\theta_{k+1} = (t_k - 1)/t_{k+1}$, $t_{k+1}(t_{k+1} - 1) = t_k^2$, with $\mathcal{T}_L x = \text{prox}_{L^{-1}h}(x - L^{-1}\nabla g(x))$ and $t_0 = 1$. This achieves $\mathcal{O}(1/k^2)$ on the objective value. Our literature review didn’t discover proofs for the convergence of the iterates. We also didn’t find proofs for a convergence rate faster than $\mathcal{O}((1 - 1/\kappa)^k)$ under strong convexity.
2. A version of FISTA where the iterates have weak convergence was proved in Chambolle, Dossal [13]. It’s a variant where $\theta_{k+1} = (n + a - 1)/a$, for $a > 2$. \mathcal{T}_L is the same as (1.).
3. Using $\theta_{k+1} = (\sqrt{\kappa} - 1)/(\sqrt{\kappa} + 1)$ where $\kappa = L/\sigma$, with σ being the strong convexity constant produces V-FISTA in Beck [2, 10.7.7][1, 3.3]. \mathcal{T}_L is the same as (1.).
4. A modification we proposed is based on (3.), but it estimates σ , the strong convexity constant based $x^{(k)}, x^{(k+1)}, \nabla f(x^{(k+1)}), f(x^{(k)})$ using

$$\sigma \approx \langle \nabla f(x^{(k+1)}) - \nabla f(x^{(k)}), x^{(k+1)} - x^{(k)} \rangle / \|x^{(k+1)} - x^{(k)}\|^2.$$

It yields excellent results for the numerical experiments.

5. MFISTA in Beck[5] is produced by adding \mathcal{S} to be the procedure

$$(y^{(k+1)}, t_{k+1}) = \begin{cases} (x^{(k+1)}, 1) & f(y^{(k+1)}) > f(x^{(k+1)}), \\ (y^{(k+1)}, t_{k+1}) & \text{else.} \end{cases}$$

This condition asserts a monotone decrease in the objective value. If the objective with momentum increases, it resets the momentum for the next iteration. It has a convergence rate of $\mathcal{O}(1/k^2)$ back then. Our review of the literature didn't confirm the existence of a proof where it has a faster convergence than $\mathcal{O}((1 - 1/\kappa)^k)$ under the presence of strong convexity.

For our problem posed in section 1, the V-FISTA algorithm variant (3.), when applied to the dual objective, achieves a convergence rate of $\mathcal{O}((1 - 1/\sqrt{\kappa})^k)$ for the function objective. For larger κ , this produces a significantly better convergence rate than gradient descent, which is $\mathcal{O}((1 - 1/\kappa)^k)$, and FISTA, which is $\mathcal{O}(1/k^2)$.

Variants (3.) is simple; unfortunately, obtaining σ in itself could be prohibitively expensive and require knowledge about the Hessian. Underestimation of σ slows down the convergence rate. This observation sparks research interest in a method that achieves approximately $\mathcal{O}((1 - 1/\sqrt{k})^k)$ linear convergence rate for strongly convex objectives and still retains $\mathcal{O}(1/k^2)$ for Lipschitz-smooth functions in general. One of the other interests is designing a unified theoretical framework to describe all variants of APG.

To address the first issue, Aujol et al.[14] proposed an automatic restart algorithm that achieves faster convergence without knowing the prior strong convexity (or weaker quadratic growth condition) parameter σ . Later, they developed the idea into a parameter-free algorithm in their work [15]. Earlier attempts proved a fast linear convergence rate under quadratic growth conditions by triggering the restart of FISTA based on the gradient mapping norm. See [16][16][17]. The interests gather around restarting FISTA because spending too much computational effort would be competing against the Proximal Quasi-Newton method, questioning the use of momentum in the first place.

On the theoretical side, Su et al. [18] identifies a second-order differential equation with the exact limit of (1.). A dynamical system understanding of FISTA and APG, in general, enables a wider variety of mathematical tools. For example, in Attouch and Peypouquet [19], they showed a $o(1/k^2)$ convergence rate of variant (2.) based on the ODE understanding. We emphasize that it's the little-o and not the big-O. In Nesterov[3], he proposed a generic algorithm that can derive variants (1.), (3.), and more using the idea of Estimating Sequences and Functions. He constructed a proof of convergence on his generic algorithm, demonstrating both linear and sub-linear convergence rates (depending on the parameter) on the functions' objective value without assuming the minimizers' existence. For Nesterov's involvement in proving convergence of APG in the non-convex settings, consult [20]. Finally, for a theoretical underpinning of Nesterov's generic method in his book, consult Ahn and Sra[21]. They derived a lot of variants of APGs using the Proximal Point method of Rockafellar and discussed the unified theme of a "similar triangle" behind the Nesterov APG method.

3 Nesterov's Lower Bound Clarified

Nesterov discussed his claim of the lower convergence rate for the first-order method on differentiable function in his book[12]. Walkington[1] rephrased his work with one crucial mistake in understanding Nesterov's claim. We detail Nesterov's claim and provide context for understanding the mistakes in Walkington. We use the following notations

1. Let $\mathcal{A}_f^k x^{(0)}$ denotes the solution of the k -th iterate $x^{(k)}$ generated by an algorithm $\mathcal{A} \in \text{GA}^{1\text{st}}$, with initial guess $x^{(0)}$, objective function f . With this notation, $x^{(1)} = \mathcal{A}_f x^{(0)}$ and $(\mathcal{A}_f^k x^{(0)})_{k \in \mathbb{N}}$ denotes the sequence generated by $\mathcal{A} \in \text{GA}^{1\text{st}}$, with f .
2. Let $\mathcal{F}_L^{1,1}$ denote the set of convex functions with L -Lipschitz gradient mapping from \mathbb{R}^n to \mathbb{R} .

3.1 First-order Method

The following is rephrased from Assumption [3, 2.1.4].

Definition 1 (First Order Method). We are in \mathbb{R}^n for now. Given $x^{(0)} \in \mathbb{R}^n$, an iterative algorithm generates sequence of $(x^{(n)})_{n \in \mathbb{N}}$ in the space. All $\mathcal{A} \in \text{GA}^{1\text{st}}$ satisfy that

$$x^{(j+1)} := \mathcal{A}_f^{j+1} x^{(0)} \in \left\{ x^{(0)} \right\} + \text{span} \left\{ \nabla f \left(x^{(i)} \right) \right\}_{i=1}^{j-1} \quad \forall f, \forall 1 \leq j \leq k-1.$$

We came up with the following example to illustrate the definition.

Example 3.1 (Fixed Step Descent). The method of fixed-step gradient descent, $x^{(k+1)} = x^{(k)} - L^{-1} \nabla f(x^{(k)})$ is $\bar{\mathcal{A}} \in \text{GA}^{1\text{st}}$ achieves a maximal decrease in objective value for all $f \in \mathcal{F}_L^{1,1}$ given $x^{(k)}$, it can be understood as

$$\bar{\mathcal{A}} \in \underset{\mathcal{A} \in \text{GA}^{1\text{st}}}{\text{argmin}} \max_{f \in \mathcal{F}_L^{1,1}} \left\{ f \left(\mathcal{A}_f x^{(k)} \right) \right\}.$$

This method is memoryless because it only matters what $x^{(k)}$, prior iterate $x^{(i)}, 1 \leq i \leq k-1$ plays no role.

Example 3.2 (Steepest Descent). Fix some $f, x^{(k)}$, the method of steepest descent would be $\bar{\mathcal{A}} \in \text{GA}^{1\text{st}}$ and it's

$$\bar{\mathcal{A}} \in \underset{\mathcal{A} \in \text{GA}^{1\text{st}}}{\text{argmin}} \left\{ f \left(\mathcal{A}_f x^{(k)} \right) \right\}.$$

This method is also memoryless.

Other methods of $\text{GA}^{1\text{st}}$ include Conjugate Gradient, Quasi-Newton, and Gradient Descent with Momentum.

3.2 Lower Complexity Bounds for L -Lipschitz Smooth Function

The following is Nesterov [3, Thm 2.1.7].

Theorem 3.2.1 (Nesterov's Claim of Lower Bound). For any $1 \leq k \leq 1/2(n-1)$, for all $x^{(0)} \in \mathbb{R}^n$, there exists a Lipschitz smooth convex function in \mathbb{R}^n such that for all algorithm from $\text{GA}^{1\text{st}}$, we have the lower bound for the optimality gap for the function values and its iterates:

$$f \left(x^{(k)} \right) - f^* \geq \frac{3L \|x - x^*\|^2}{32(k+1)^2}, \quad \|x^{(k)} - x^*\| \geq \frac{1}{8} \|x^{(0)} - x^*\|.$$

Where x^* is the minimizer of f , so that $f(x^*) = \inf_x f(x)$.

Remark 3.2.1. We emphasize that in [theorem 3.2.1](#) fixes each k and finds a function f such that the lower bound applies at the k -th iterations. Mathematically, it would mean

$$\begin{aligned} \forall 1 \leq k \leq \frac{n+1}{2}, x^{(0)} \in \mathbb{R}^n \exists f \in \mathcal{F}_L^{1,1} \text{ s.t.: } \min_{\mathcal{A} \in \text{GA}^{1\text{st}}} \left\{ f \left(\mathcal{A}_f^k x^{(0)} \right) \right\} - f^* &\geq \frac{3L \|x^{(0)} - x^*\|^2}{32(k+1)^2} \\ \forall 1 \leq k \leq \frac{n+1}{2}, x^{(0)} \in \mathbb{R}^n \max_{f \in \mathcal{F}_L^{1,1}} \min_{\mathcal{A} \in \text{GA}^{1\text{st}}} \left\{ f \left(\mathcal{A}_f^k x^{(0)} \right) - f^* \right\} &\geq \frac{3L \|x^{(0)} - x^*\|^2}{32(k+1)^2} \\ \forall x^{(0)} \in \mathbb{R}^n \min_{1 \leq k \leq 1/2(n+1)} \max_{f \in \mathcal{F}_L^{1,1}} \min_{\mathcal{A} \in \text{GA}^{1\text{st}}} \left\{ f \left(\mathcal{A}_f^k x^{(0)} \right) - f^* \right\} &\geq \frac{3L \|x^{(0)} - x^*\|^2}{32(1/2(n+1))^2}, \end{aligned}$$

A function f_k provides the lower bound for fixed $1 \leq k \leq (n+1)/2$. k parameterized f_k , which Nesterov did in his proof. We emphasize that f_k is different depending on what k is. In addition, observe that minimizer x^* is assumed to exist.

We are unsure how the theorem generalizes to infinite dimension Hilbert space due to the assumption of x^* and the function Nesterov used in his proof.

We now quote Walkington [1, theorem 2.4]

Theorem 3.2.2 (Walkington’s Claim of Lower Bound). Let X be an infinite-dimensional Hilbert Space and set $x^{(0)} = \mathbf{0}$. There exists a convex function $f : X \mapsto \mathbb{R}$ with Lipschitz gradient and minimum $f(x_*) > -\infty$ such that for any sequence satisfying

$$x_{i+1} \in \text{Span} \left\{ \nabla f(x^{(0)}), \nabla f(x^{(1)}), \dots, \nabla f(x^{(i)}) \right\}, \quad i = 0, 1, 2, \dots,$$

there holds

$$\min_{1 \leq i \leq n} f(x_i) - f(x_*) \geq \frac{3L\|x_1 - x_*\|^2}{32(n+1)^2},$$

where L is the Lipschitz constant of the gradient.

Remark 3.2.2.
